

# Tackling The Reproducibility Crisis In Ecology

ESA Annual Meeting 2024

Peter Levy, UK Centre for Ecology & Hydrology

2024-08-07

# Outline

1. The Reproducibility Crisis - what is it?
2. Causes: the information architecture of science
3. Causes: high “false discovery” rates
4. Ecological examples
5. Solutions: a change in perspective in statistical thinking

# The Reproducibility Crisis

Reproducibility  
of **results**,  
not methods.

Better name:  
“*Credibility crisis*”?

## Why Most Published Research Findings Are False

John P. A. Ioannidis

**Summary**

There is increasing concern that most current published research findings are false. The probability that a research claim is true may depend on study power and bias, the number of other studies on the same question, and, importantly, the ratio of true to no relationships among the relationships probed in each scientific field. In this framework, a research finding is less likely to be true when the studies conducted in a field are smaller; when effect sizes are smaller; when there is a greater number and lesser preselection of tested relationships; when there is greater flexibility in designs, definitions, outcomes, and analytical modes; when there is greater financial and other interest and prejudice; and when more teams are involved in a scientific field in chase of statistical significance. Simulations show that for most study designs and settings, it is more likely for a research claim to be false than true. Moreover, for many current scientific fields, claimed research findings may often be simply accurate measures of the prevailing bias. In this essay, I discuss the implications of these problems for the conduct and interpretation of research.

factors that influence this problem and some corollaries thereof.

**Modeling the Framework for False Positive Findings**

Several methodologists have pointed out [9–11] that the high rate of nonreplication (lack of confirmation) of research discoveries is a consequence of the convenient, yet ill-founded strategy of claiming conclusive research findings solely on the basis of a single study assessed by formal statistical significance, typically for a *p*-value less than 0.05. Research is not most appropriately represented and summarized by *p*-values, but, unfortunately, there is a widespread notion that medical research articles is characteristic of the field and can vary a lot depending on whether the field targets highly likely relationships or searches for only one or a few true relationships among thousands and millions of hypotheses that may be postulated. Let us also consider, for computational simplicity, circumscribed fields where either there is only one true relationship (among many that can be hypothesized) or the power is similar to find any of the several existing true relationships. The pre-study probability of a relationship being true is  $R/(R+1)$ . The probability of a study finding a true relationship reflects the power  $1 - \beta$  (one minus the Type II error rate). The probability of claiming a relationship when none truly exists reflects the Type I error rate,  $\alpha$ . Assuming that  $c$  relationships are being probed in the field, the expected values of the  $2 \times 2$  table are given in Table 1. After a research finding has been claimed based on achieving formal statistical significance, the post-study probability that it is true is the positive predictive value, PPV. The PPV is also the complementary probability of what Wacholder et al. have called the false positive report probability [10]. According to the  $2 \times 2$  table, one gets  $PPV = (1 - \beta)R/(R + \beta c)$ .

**It can be proven that most claimed research findings are false.**

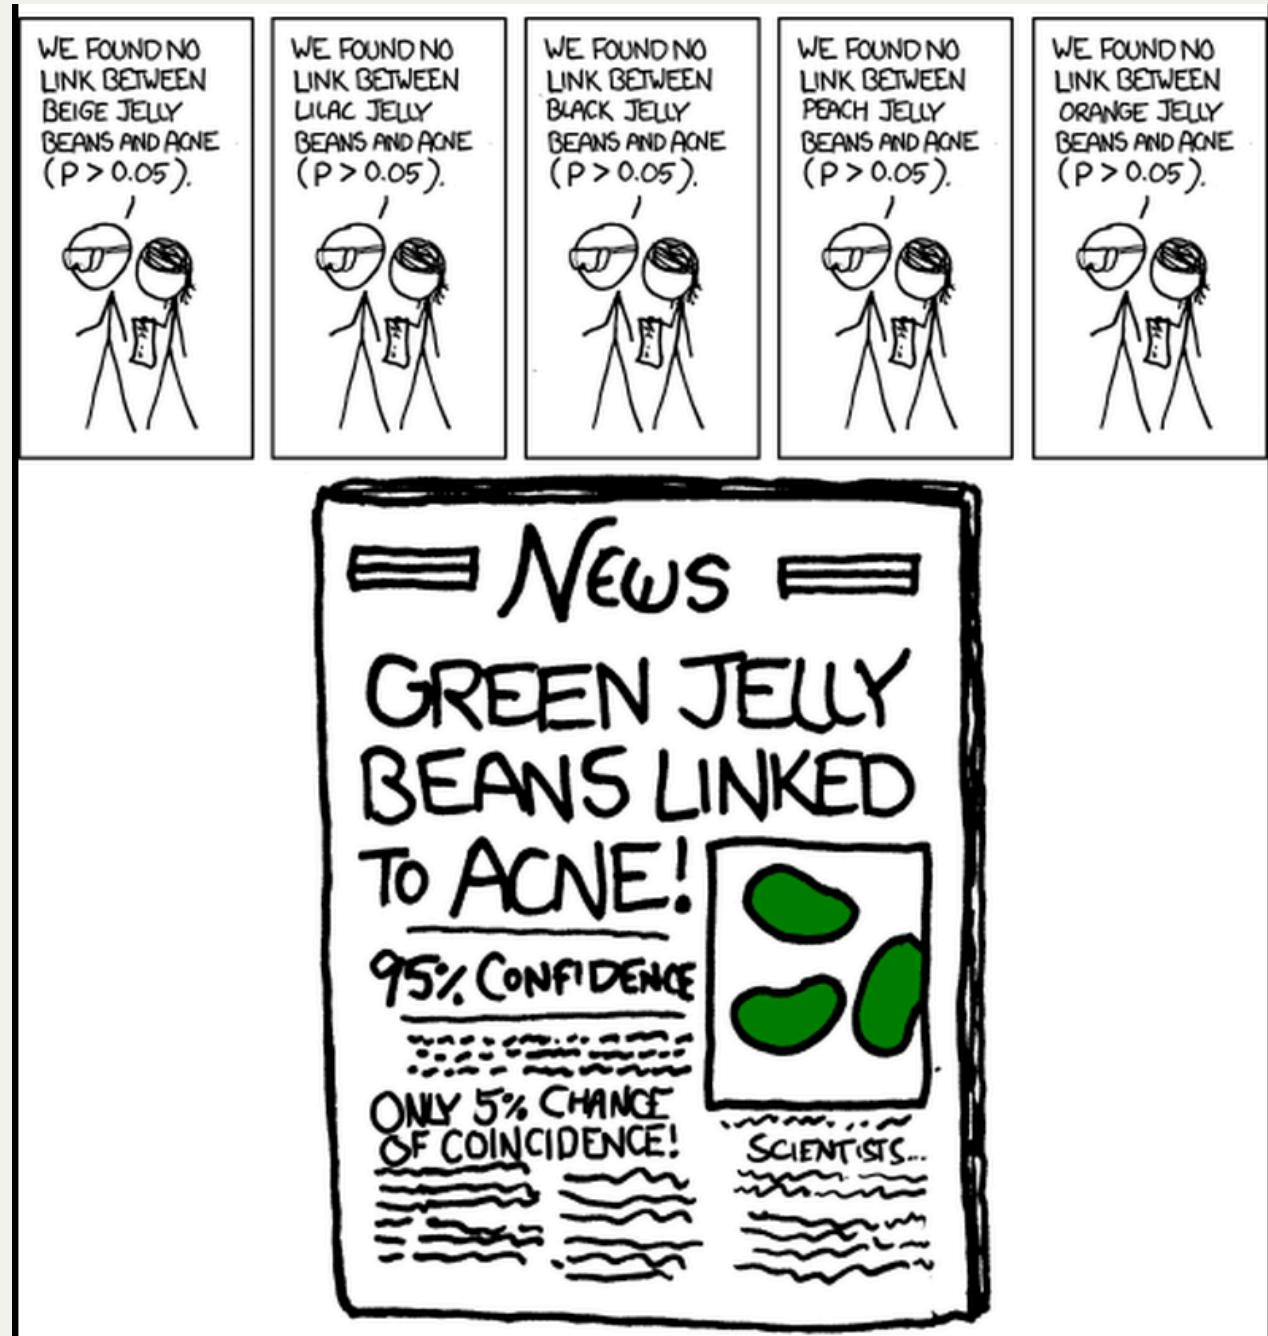

should be interpreted based only on *p*-values. Research findings are defined here as any relationship reaching formal statistical significance, e.g., effective interventions, informative predictors, risk factors, or associations. “Negative” research is also very useful. “Negative” is actually a misnomer, and

# The information architecture of science

# *“Why most published research findings are false”*

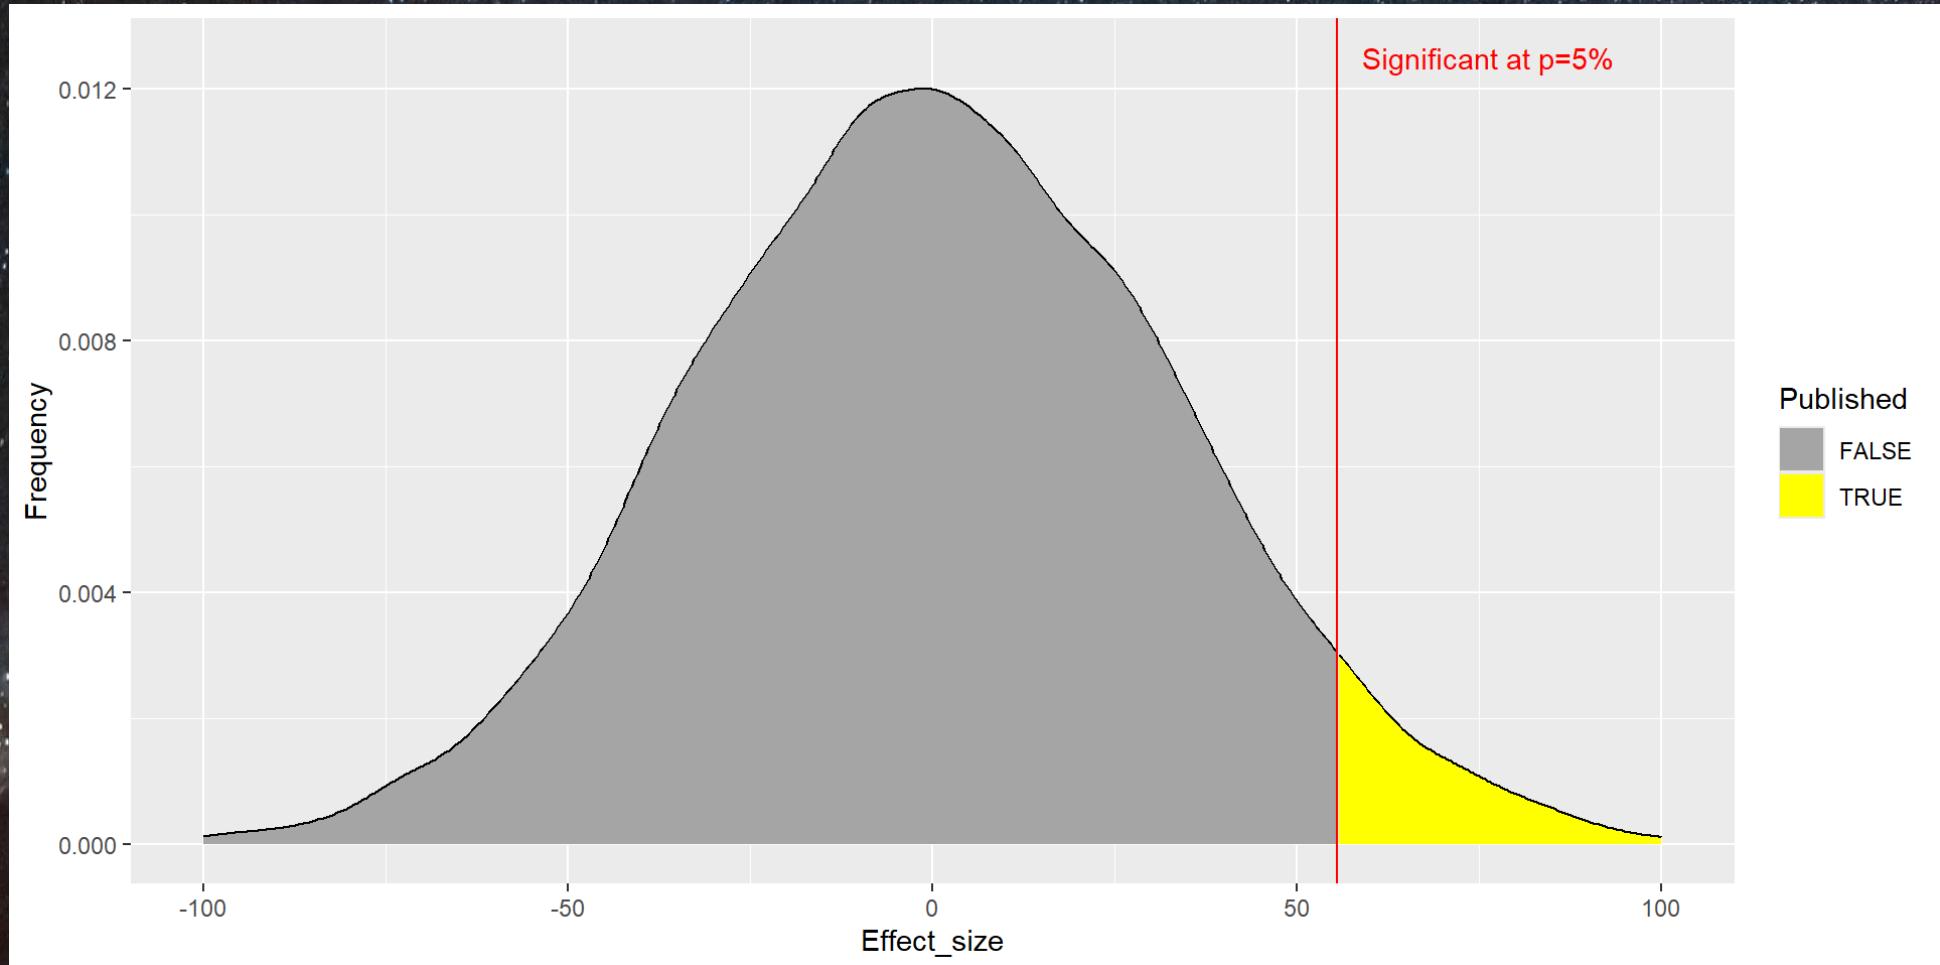

- The multiple testing problem
- What if we only publish the 5% studies with significant results?

# “Why most published research findings are false”

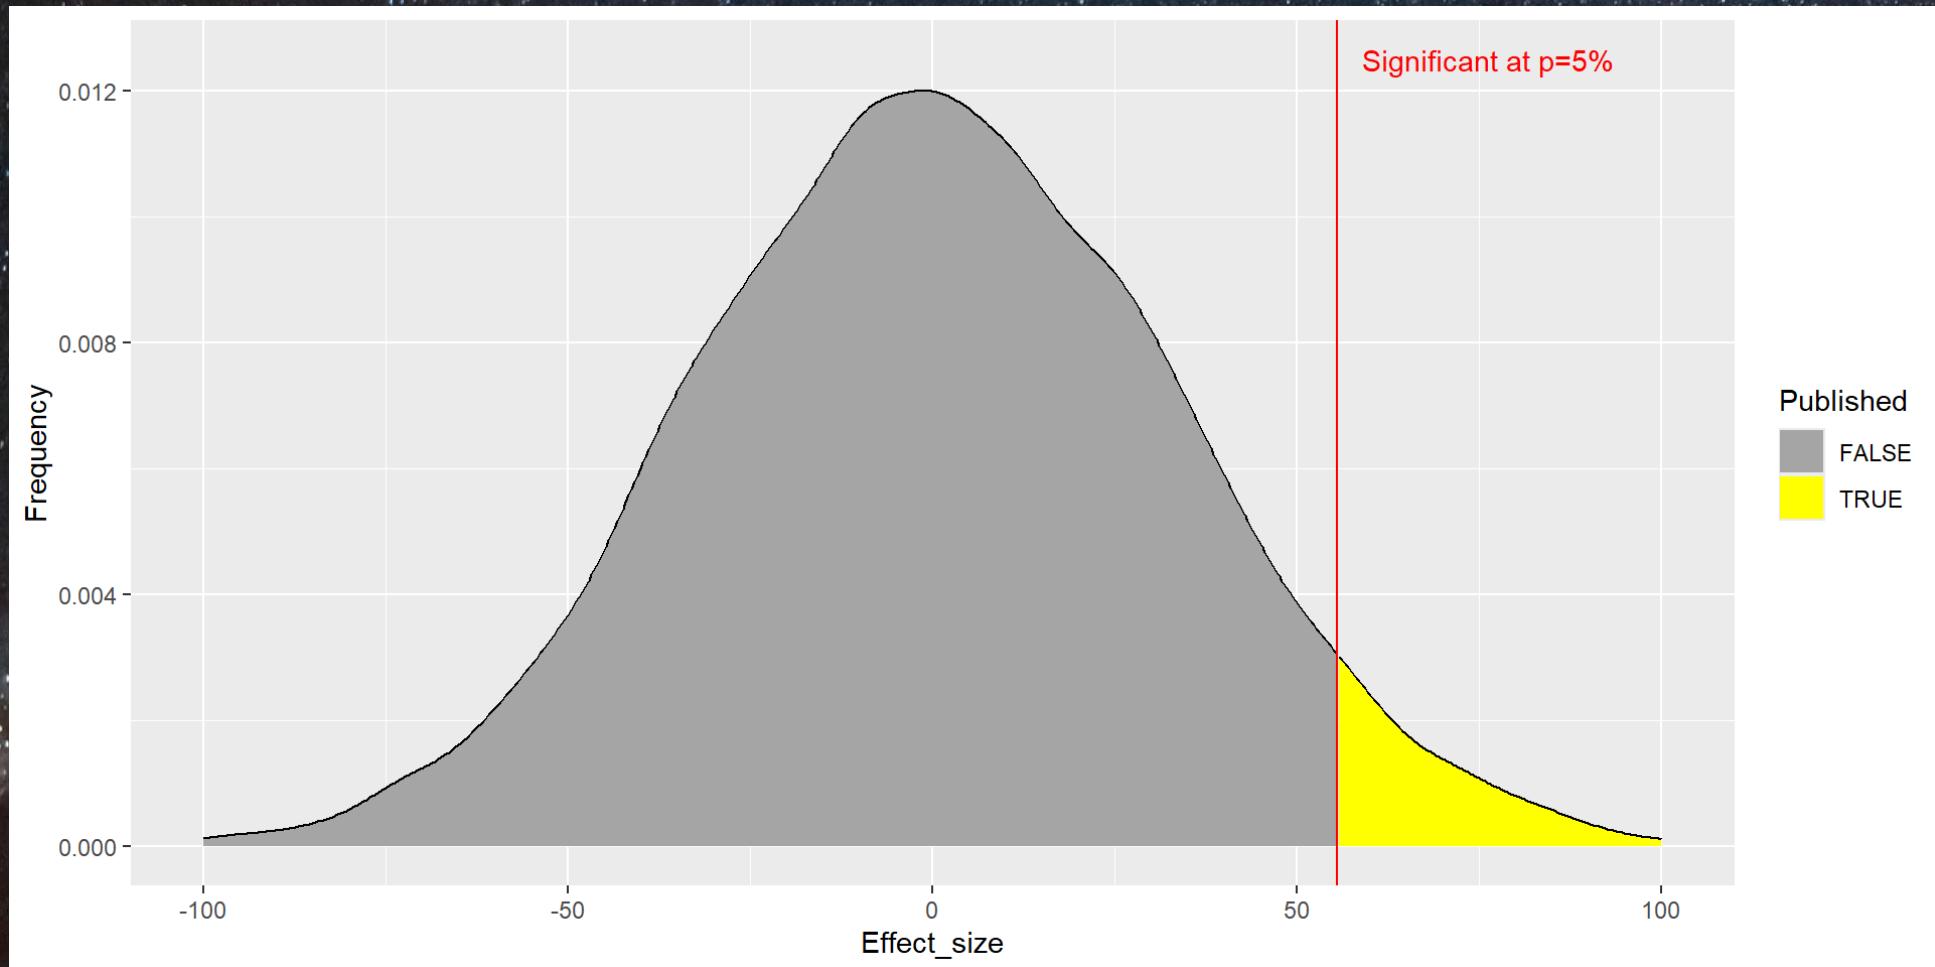

- “*The garden of forking paths*”
  - many possible choices in data collection & analysis
  - choices favour finding *interesting* patterns
- Motivated cognition
  - “the influence of motives on memory, information processing & reasoning.”
- Journals reject negative or confirmation results

# Unpublished work as Dark Matter

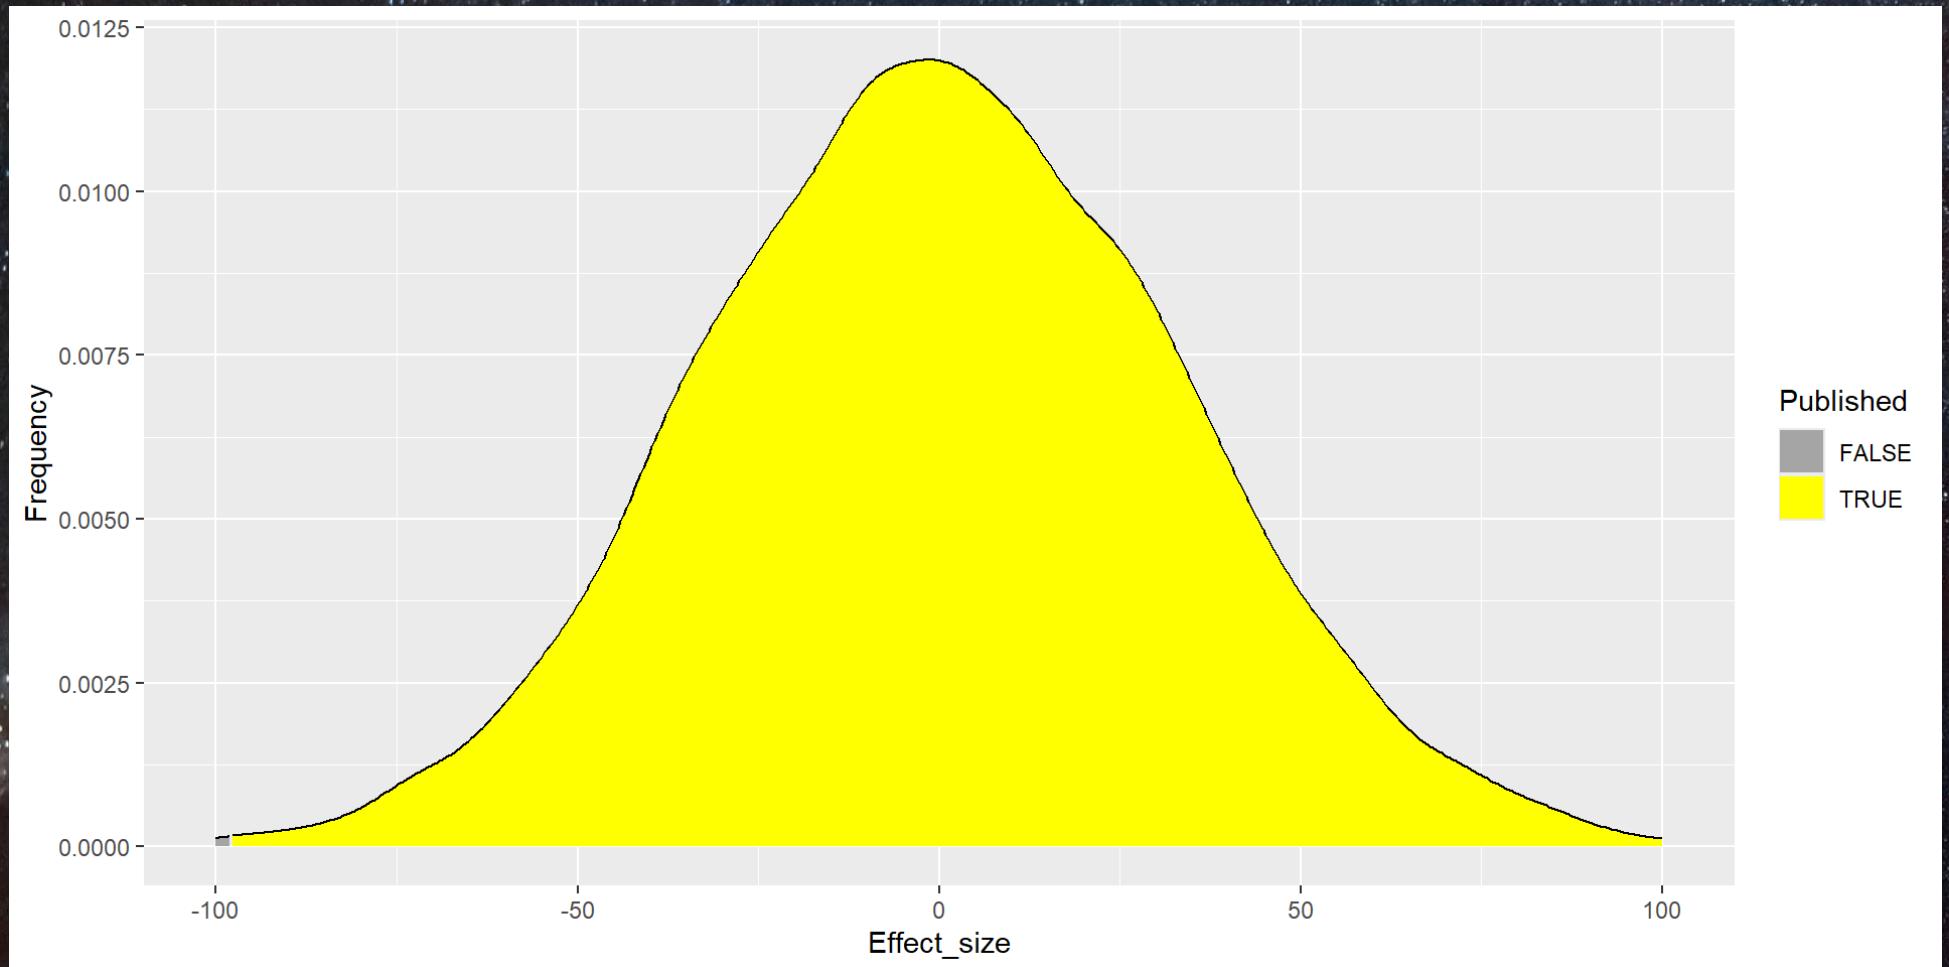

We can only see 5% of the universe.

# Solutions

Don't focus on testing a null hypothesis.

# Solutions

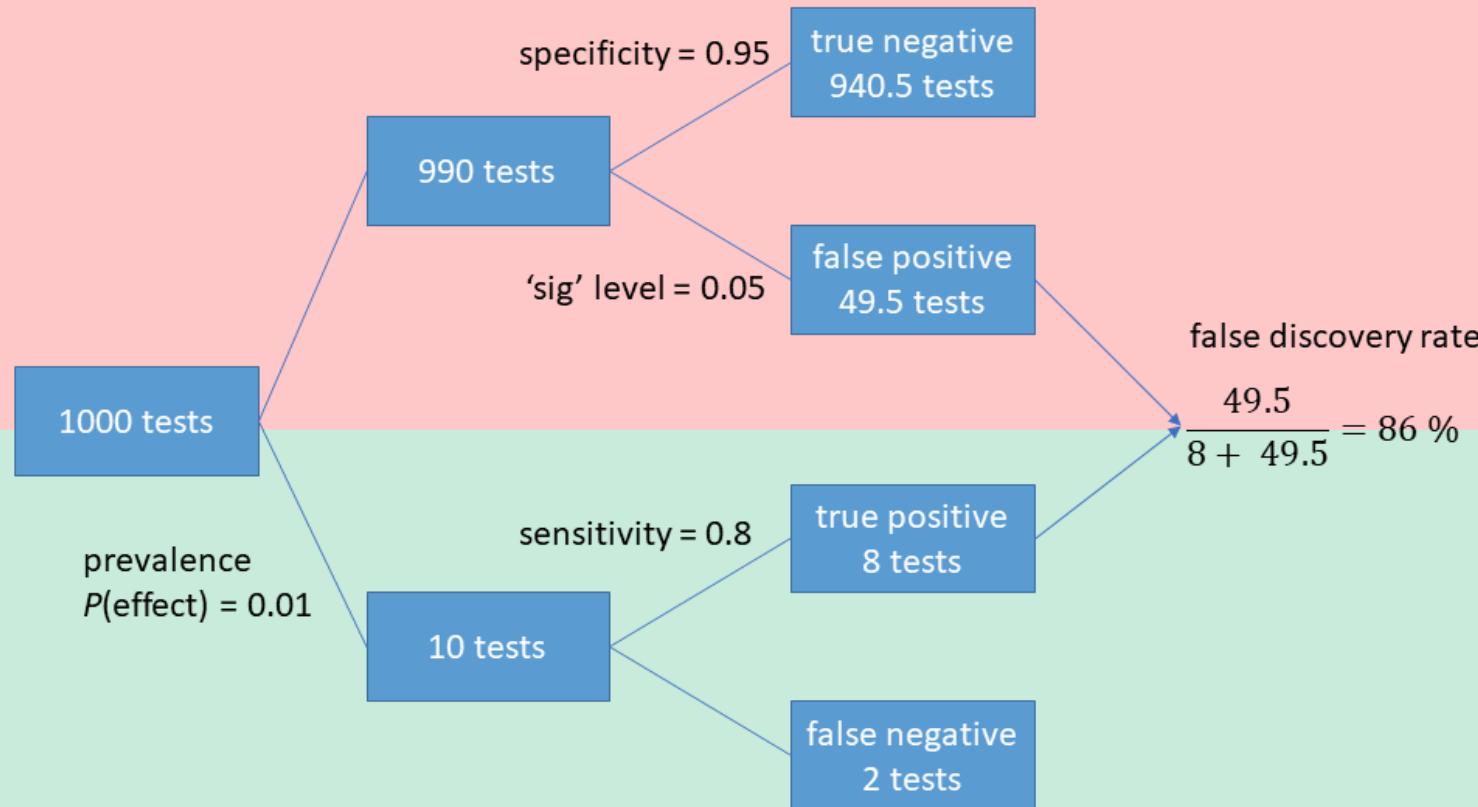

Pre-register and publish **all** results.

# False discovery rates in ecology

# *“Why most published research findings are false”*

1. Low prior probabilities - unlikely / rare effects
  2. Low statistical power - low signal:noise
  3. Bias - systematic uncertainties in observation process
- > High “false discovery rates”, often much higher than 5 %

# 1. Low prior probabilities

## Land-Use Change: just the difference between maps at two times?

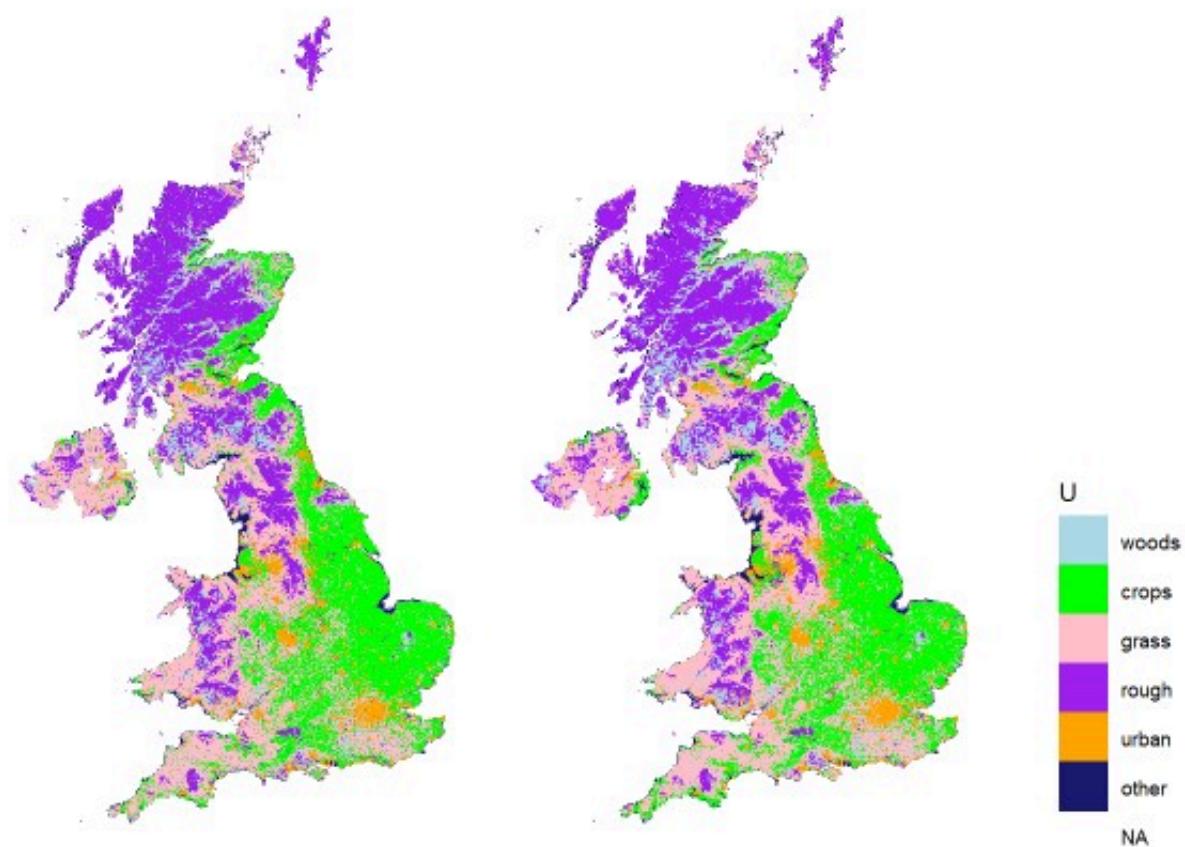

Yes, if:

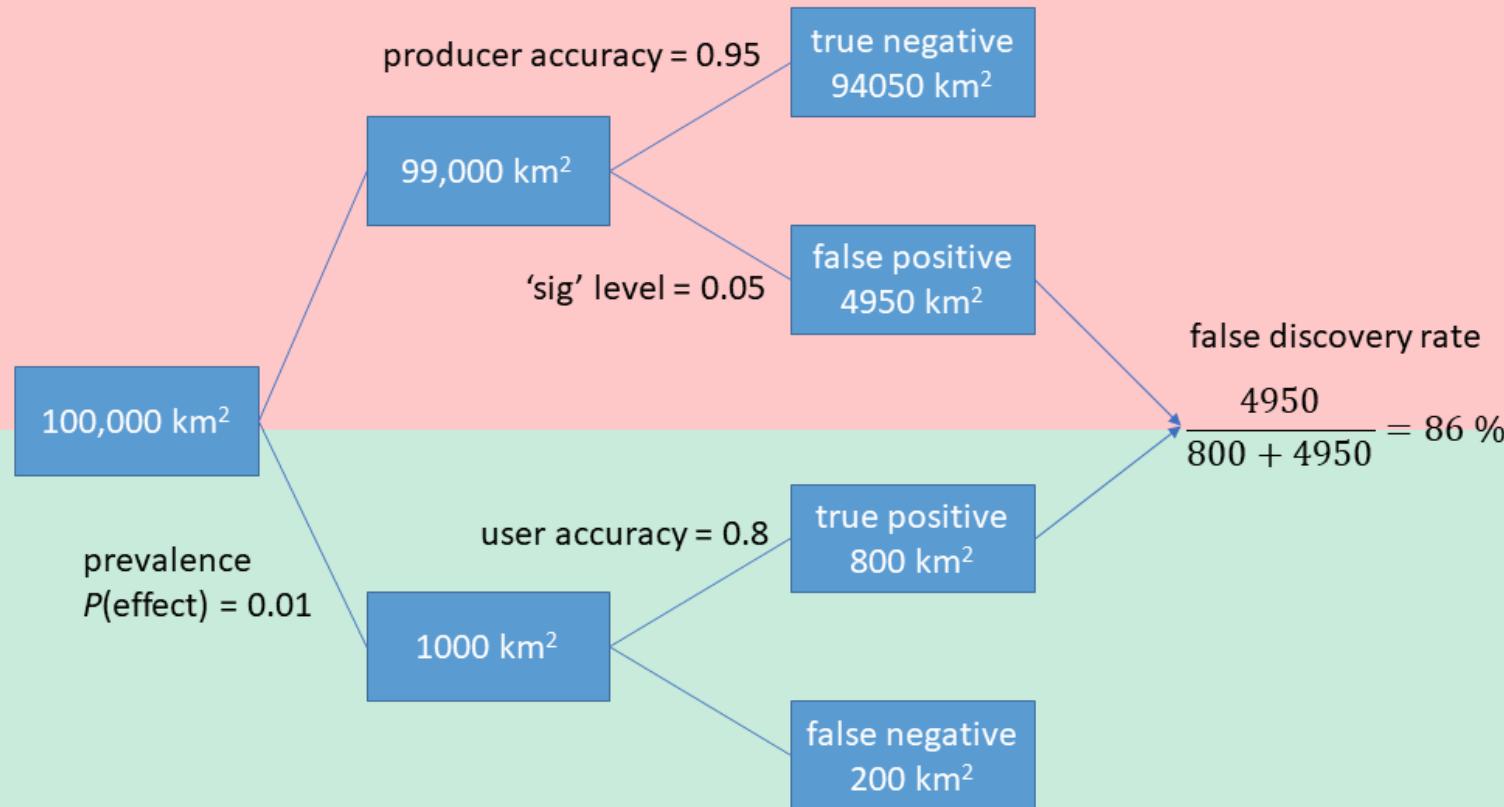

- maps are accurate
- magnitude of change is large

In UK:

- map classification accuracy is ~90%
- magnitude of change is small (<0.5%)

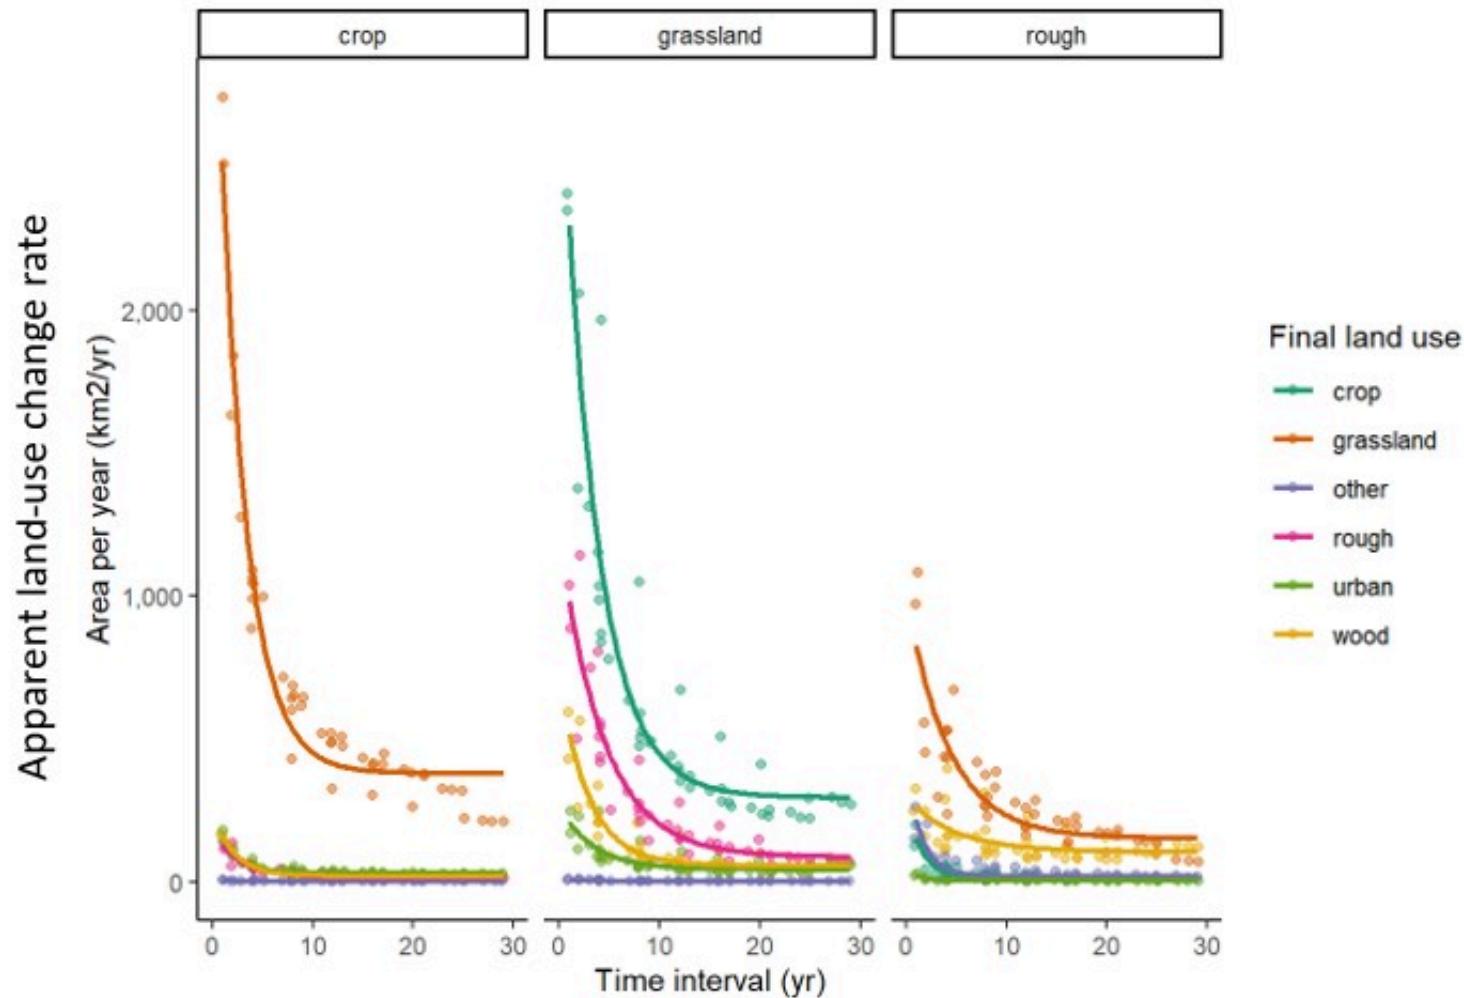

# Example: Land-use change

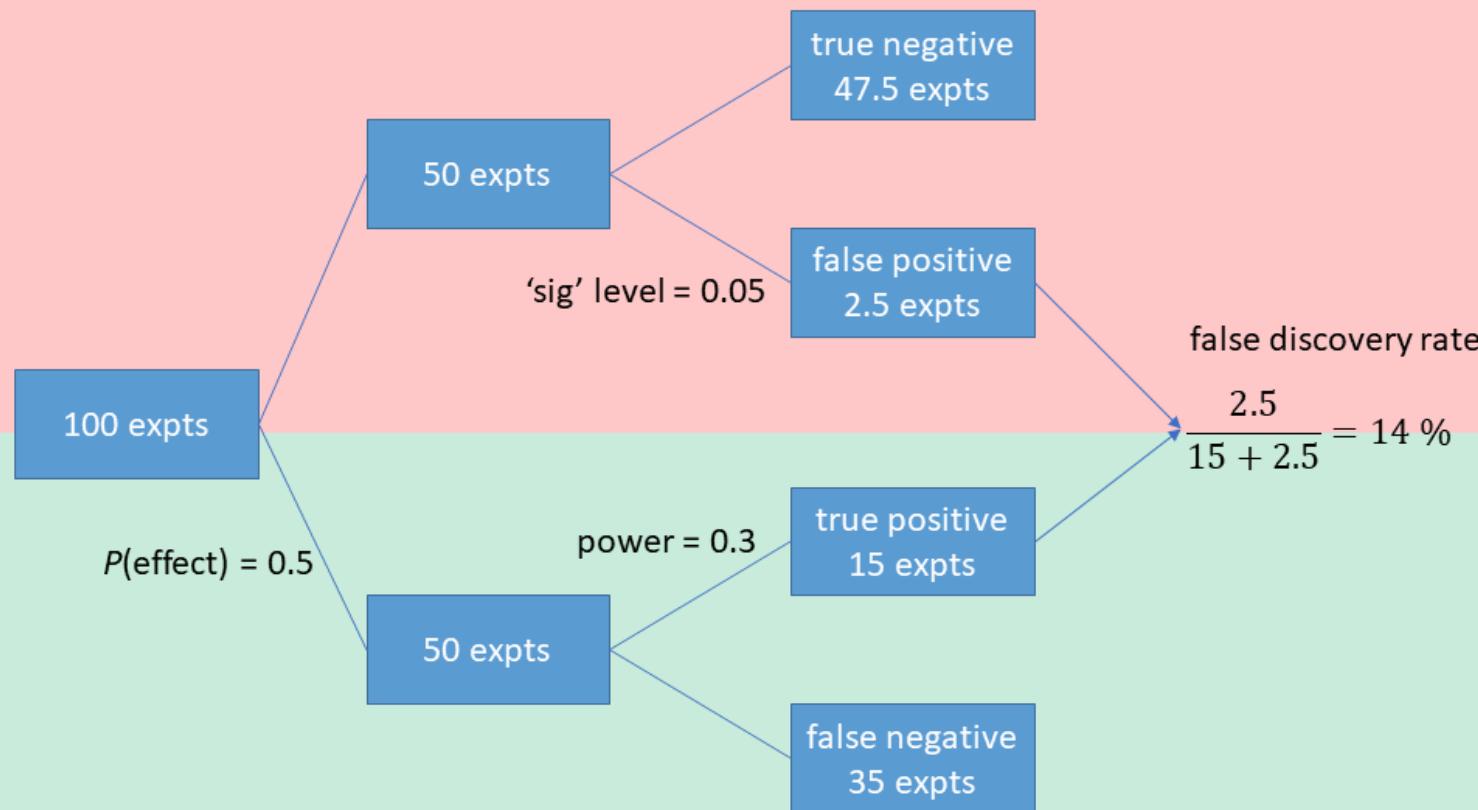

## Empirical evidence from LCM analysis

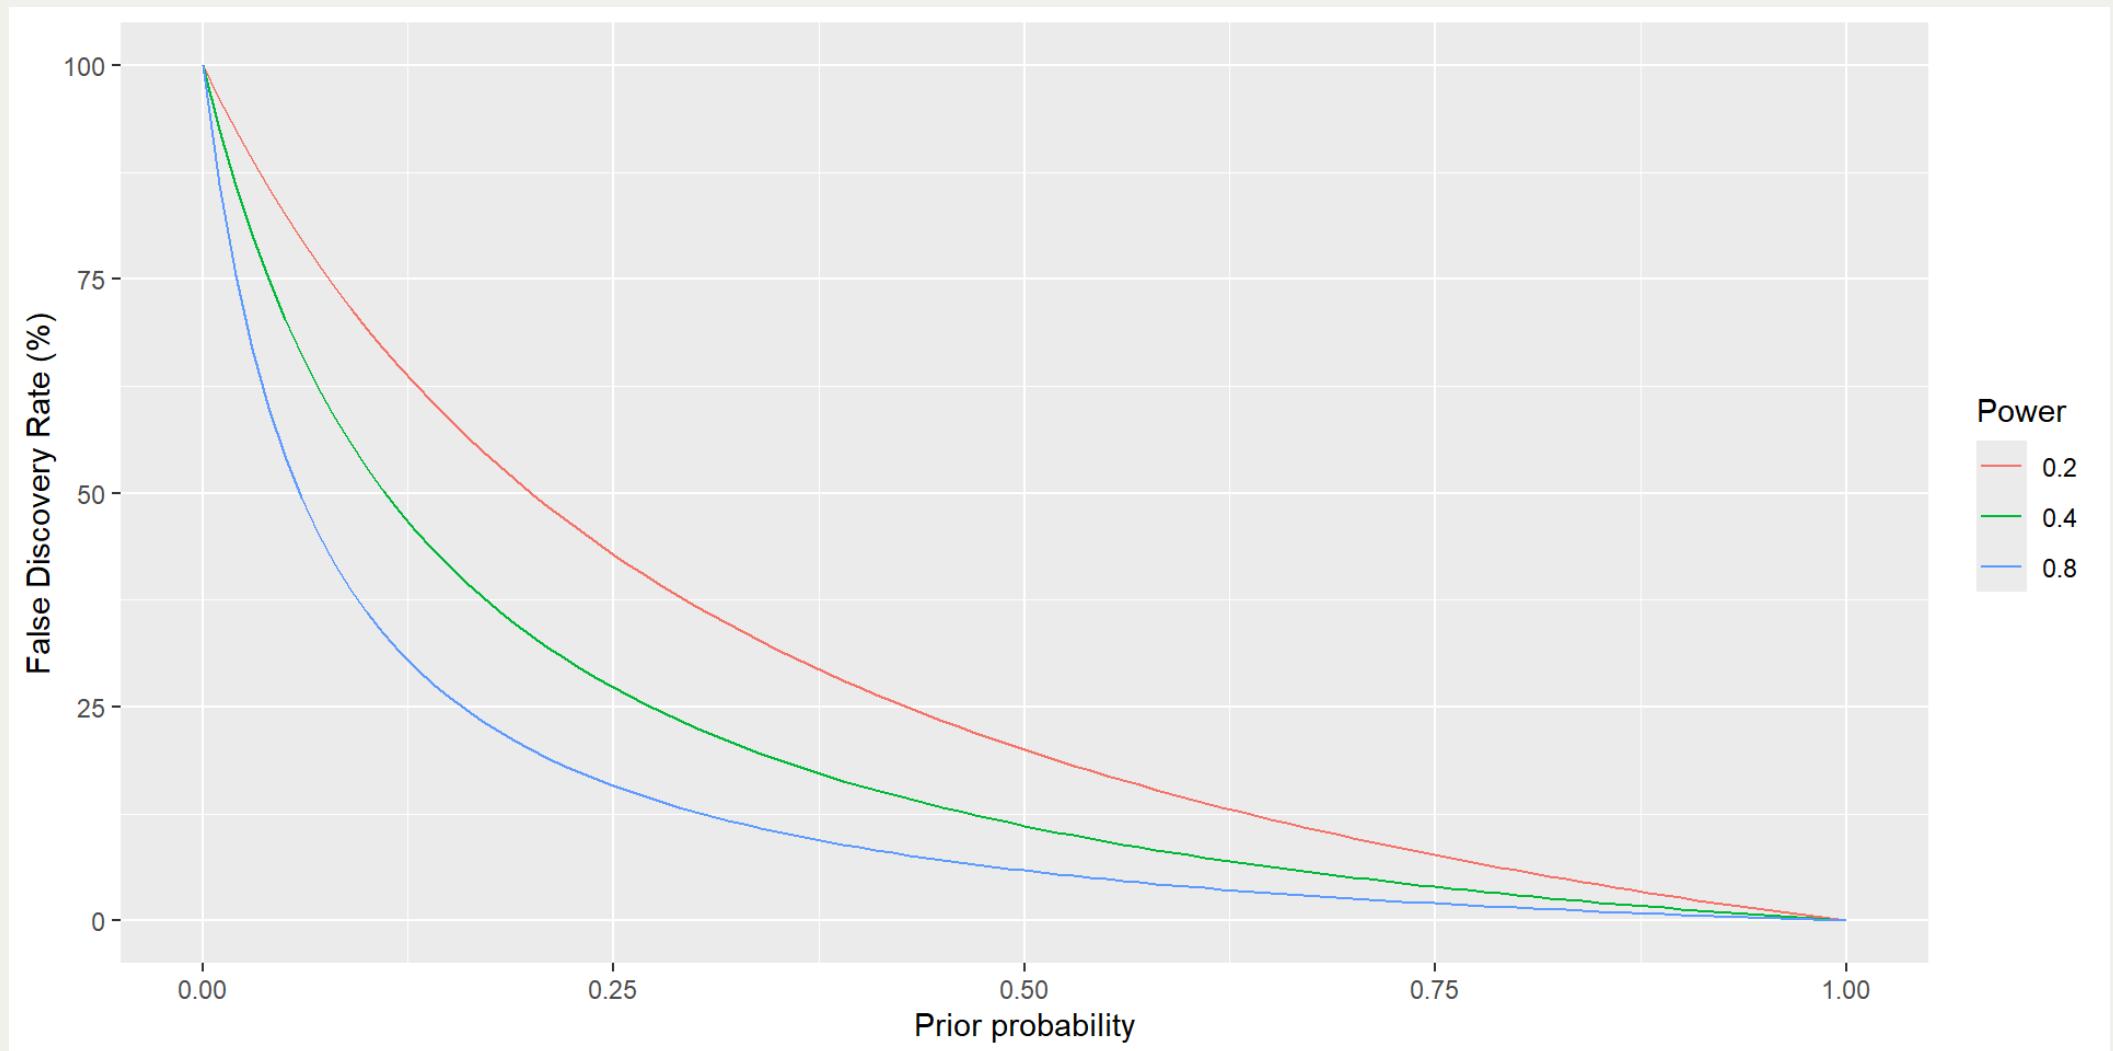

Expect horizontal line if false positive rate = 0

## 2. Low statistical power

## 2. Effect of low power

## 2. Low power in ecology

Measurements are a proxy for true process of interest.

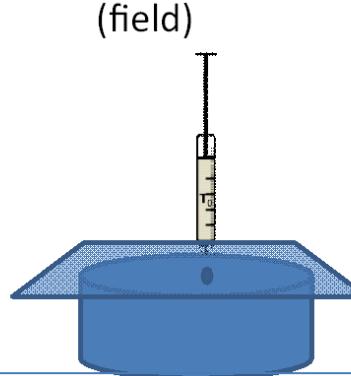

Connection between the two can be:

- sample from population (sampling error)
- imperfect measurements (measurement error)
- proxy variables
  - true variable is hard to measure but can be approximated

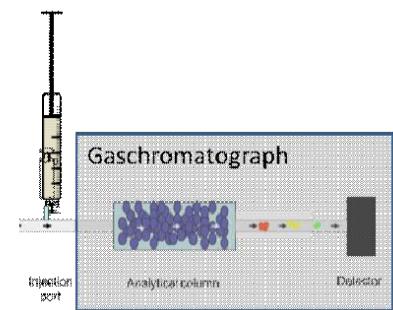

# Example: gas emissions from soil

## Measuring N<sub>2</sub>O emissions

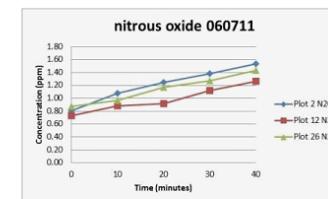

Sample collection

(laboratory)

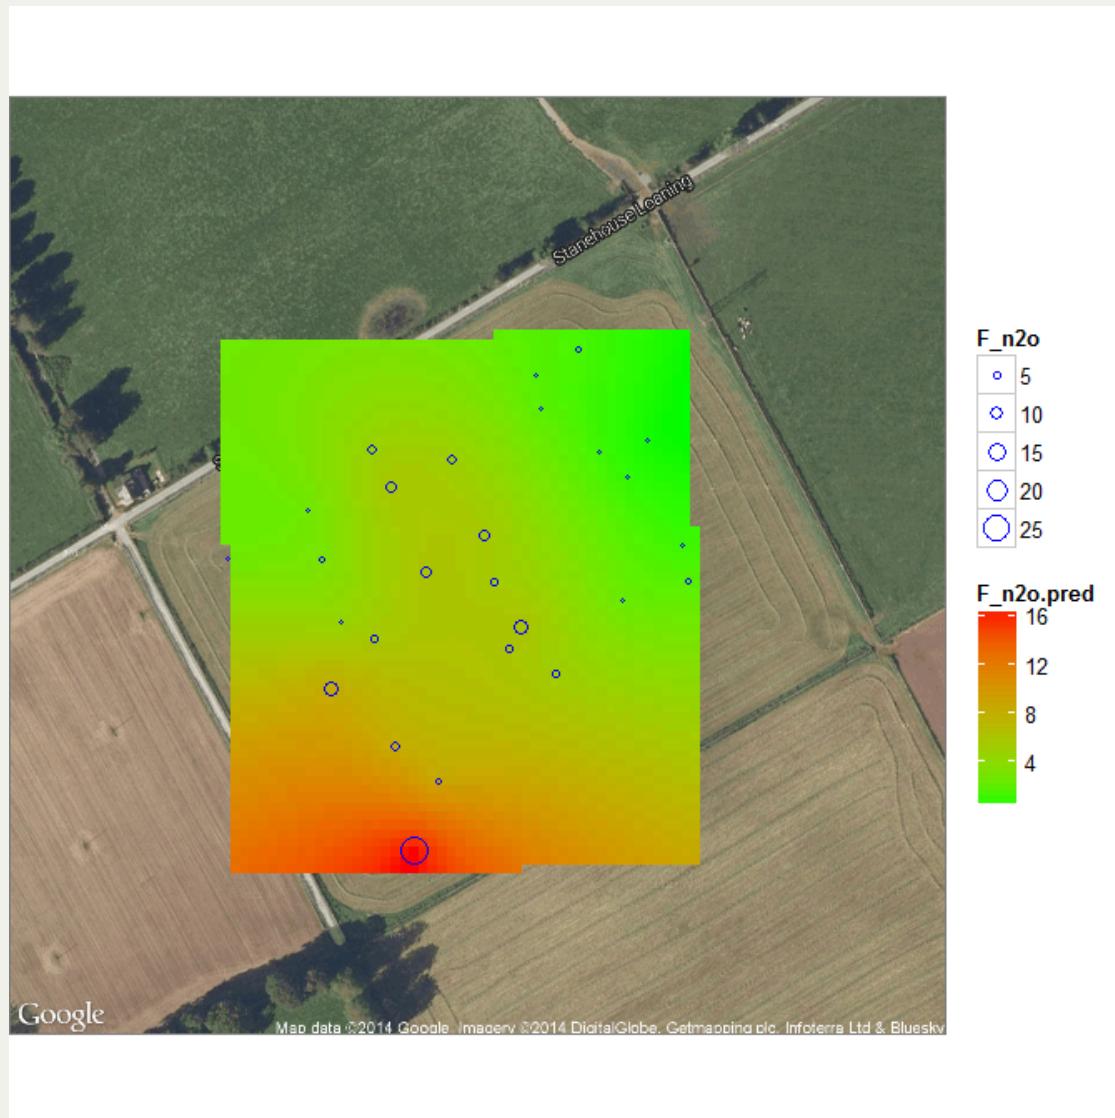

Analysis  
Flux calculation

$$F = \frac{dC}{dt_0} \frac{\rho V}{A}$$

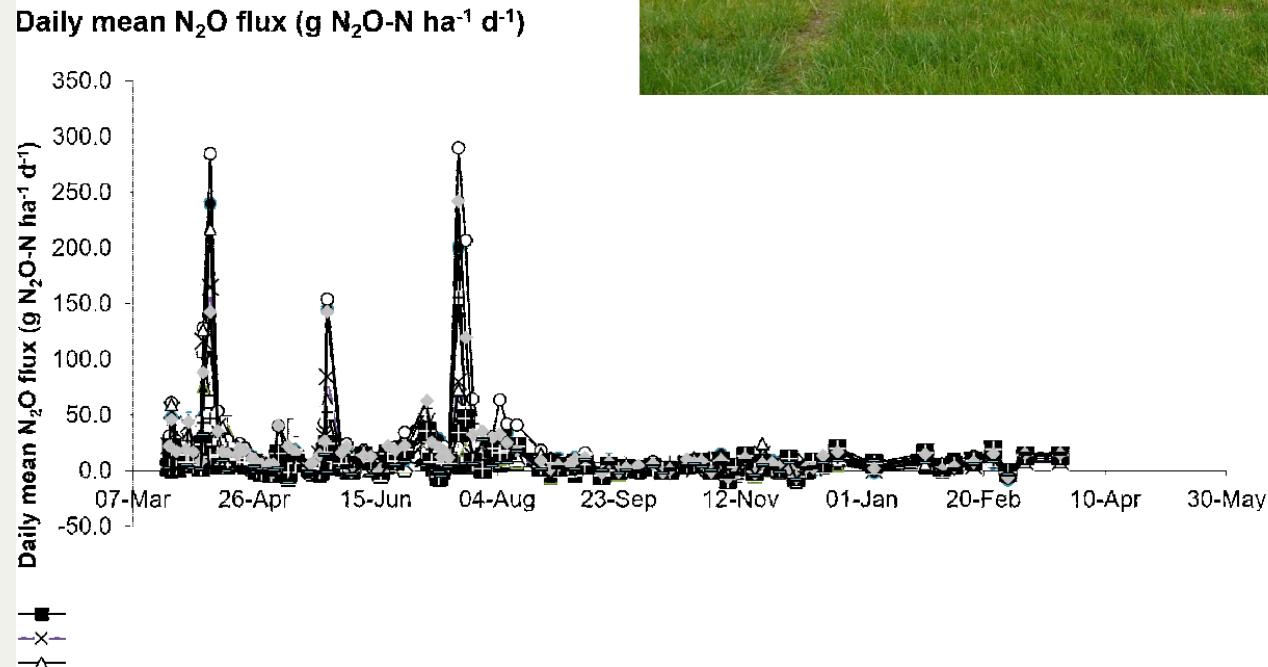

5

# Spatial variation in gas emissions

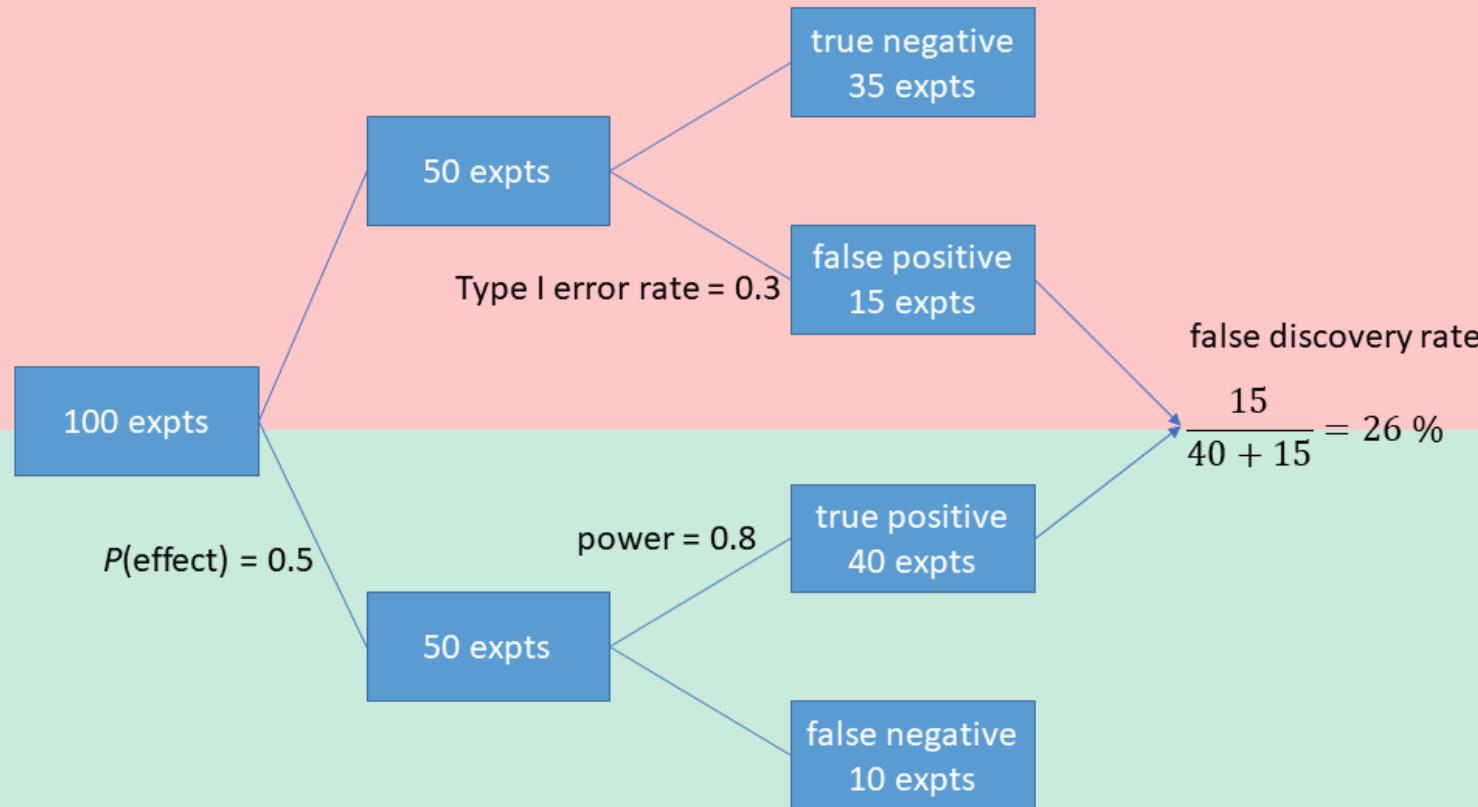

# We need cumulative emissions

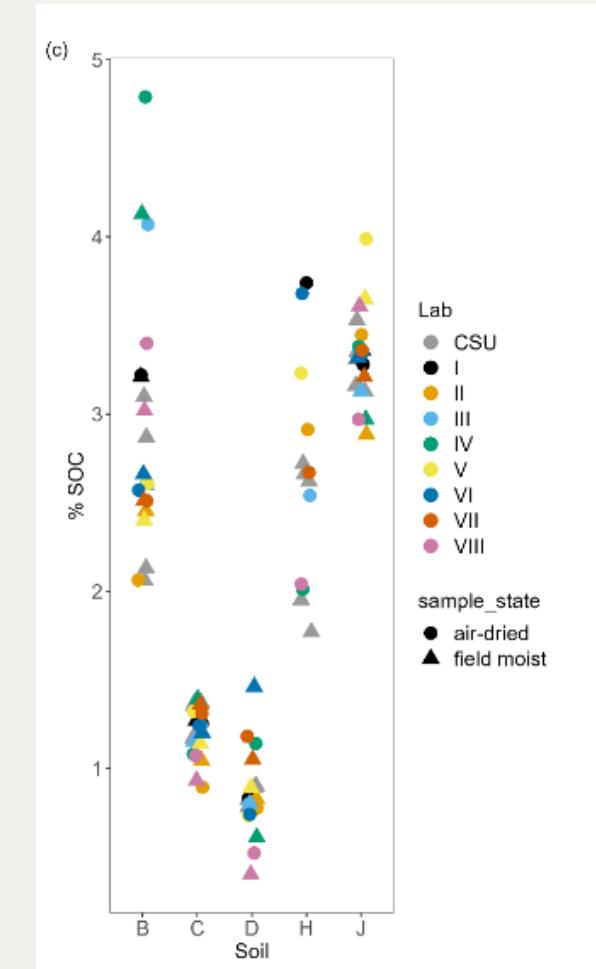

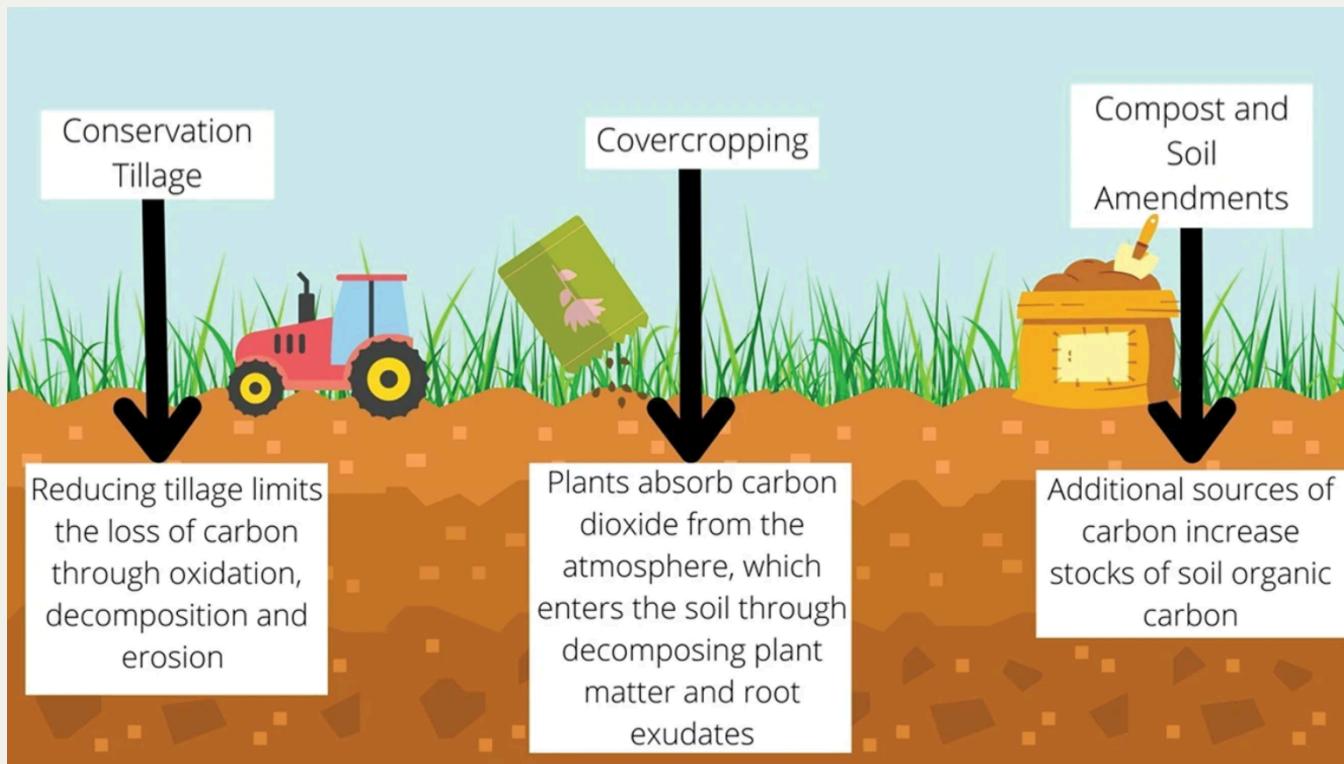

# Measuring N<sub>2</sub>O

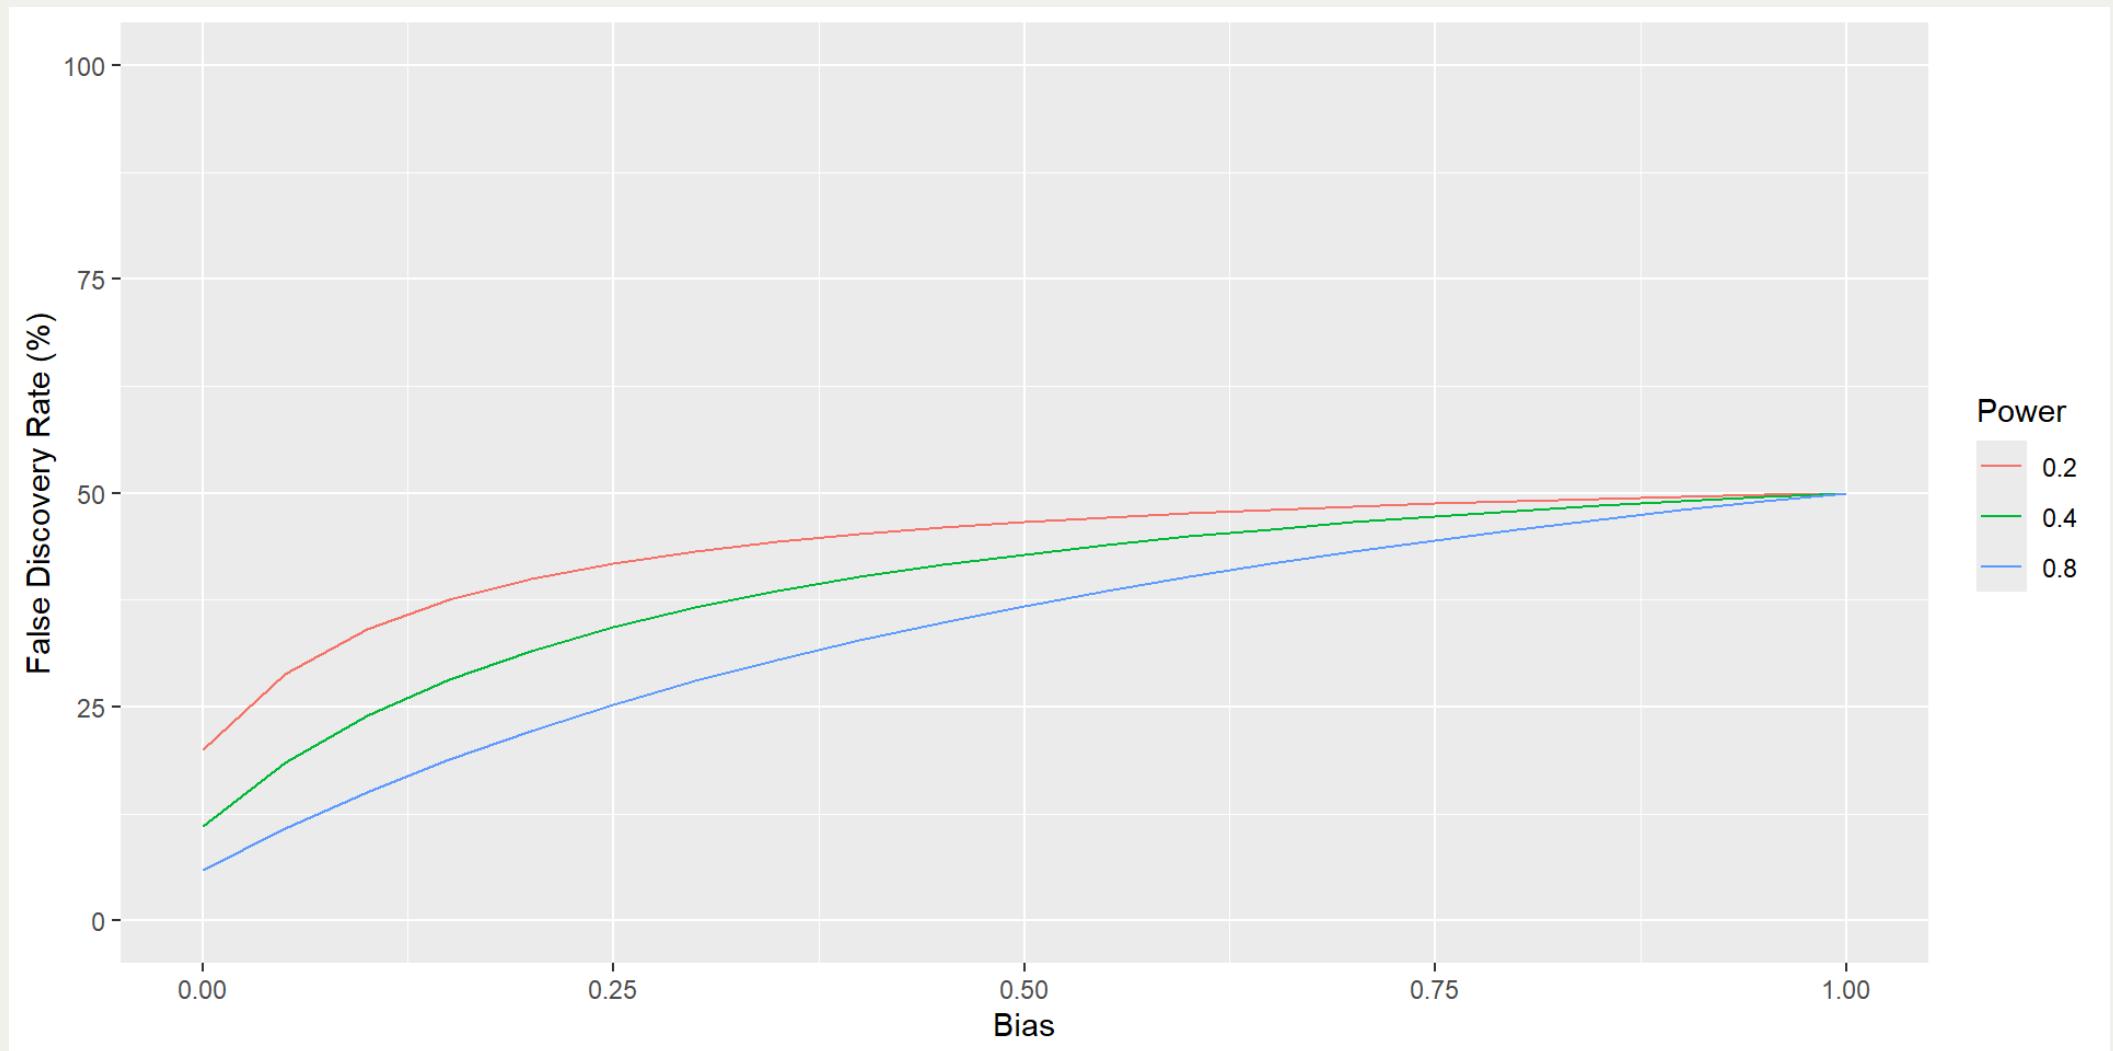

# 3. Bias in observation process

# Example: soil carbon change

# 3. Effect of bias

# Solutions

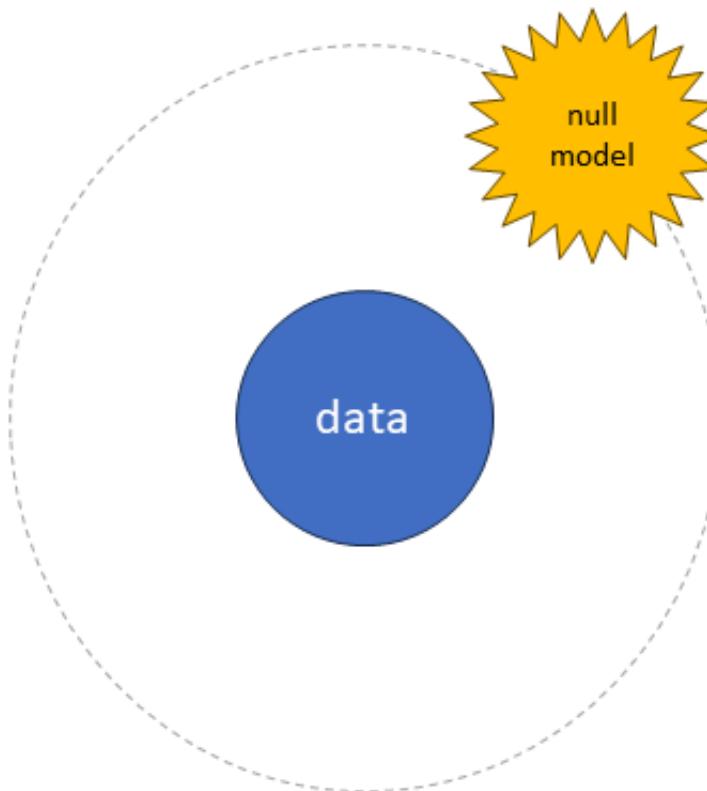

# A Copernican Revolution

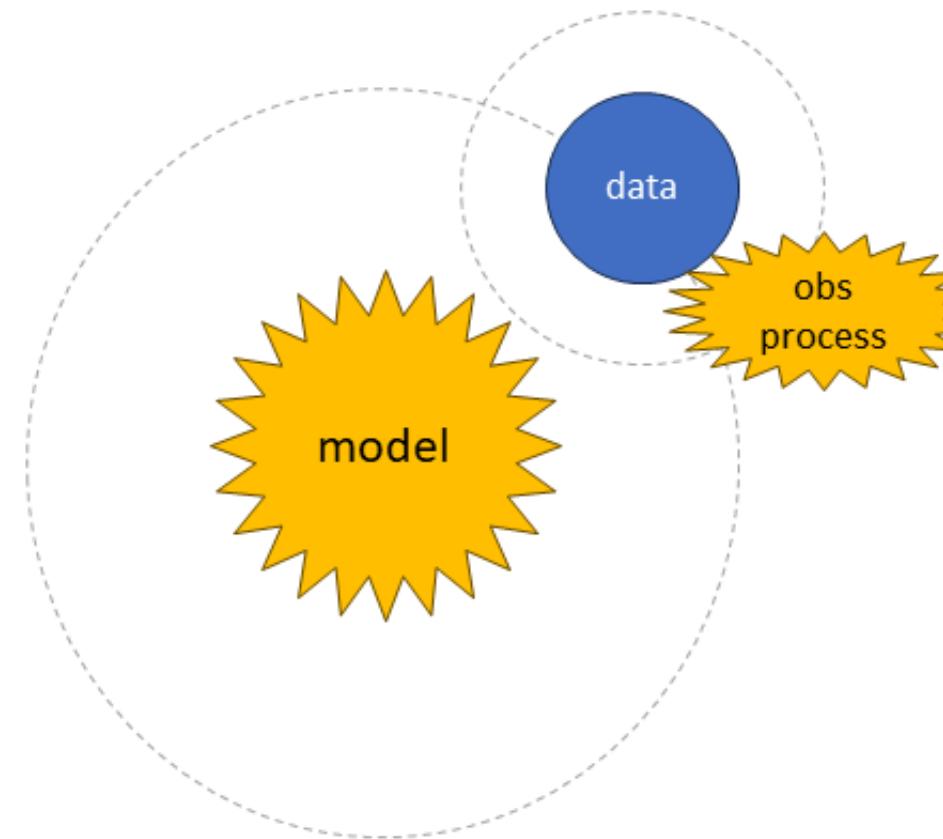

# A Copernican Revolution

Conventional statistics

Data is fixed  
Centred on  $P[\text{data} \mid \text{null model}]$

Conditional probability (Bayes rule)

Data & observation process are uncertain  
Centred on  $P[\text{model}, \text{obs process} \mid \text{data}]$

# In practice

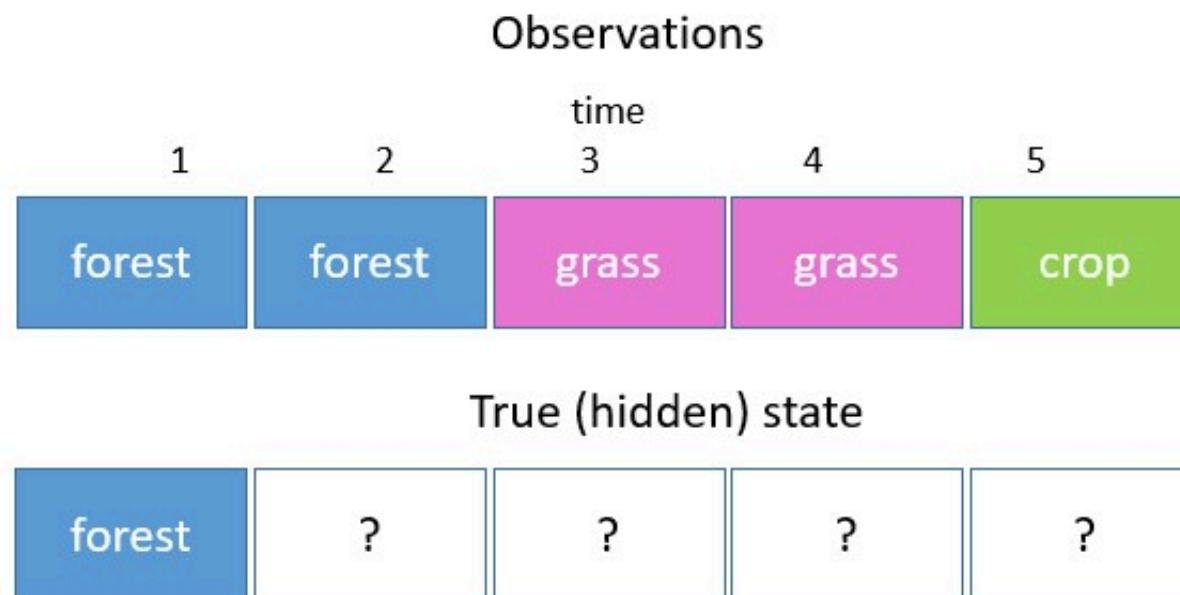

- don't take data at face value
- represent & propagate their uncertainties
- represent potential biases
- often goes beyond off-the-shelf stats model
- suits Monte Carlo or fully Bayesian approach
- examples ...

# Example: Land-Use Change

## Solution: Hidden Semi-Markov Model

The true sequence of states is **hidden**.

We want to know the probability  $P(\text{true} \mid \text{observed})$

## Solution: Hidden Semi-Markov Model

The true sequence of states is **hidden**.

We want to know the probability  $P(\text{true} \mid \text{observed})$  given:

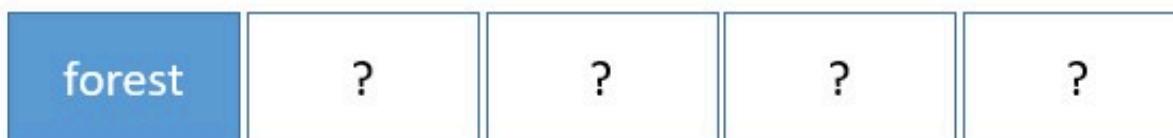

- the transition probability matrix

	Forest	Crop	Grass	To
From	Forest	0.97	0	0.03
Forest	Crop	0.02	0.8	0.18
Grass	Grass	0.02	0.08	0.9

Observations

True (hidden) state

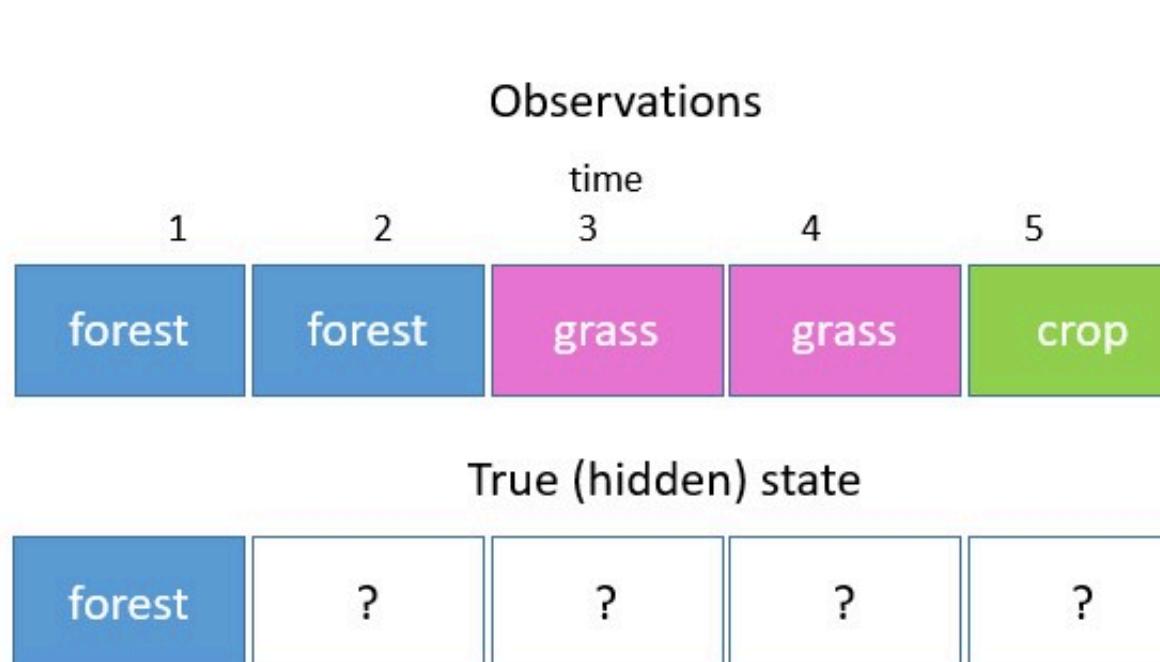

## Solution: Hidden Semi-Markov Model

The true sequence of states is **hidden**.

We want to know the probability  $P(\text{true} \mid \text{observed})$  given:

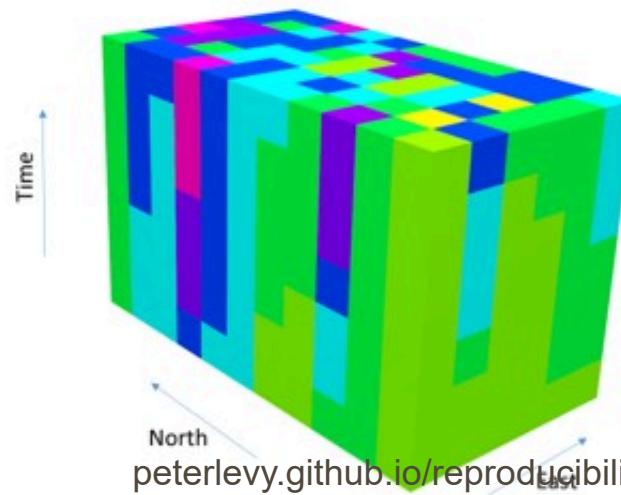

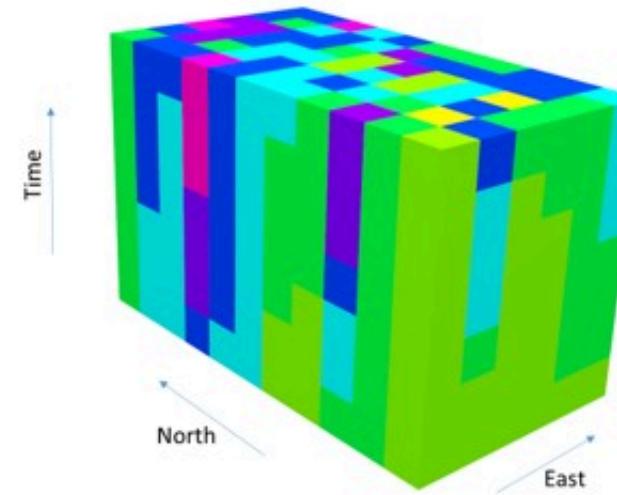

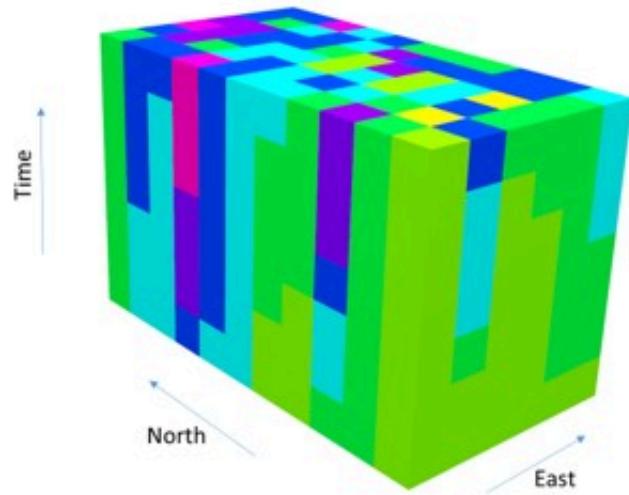

- the transition probability matrix
- the observation likelihoods  $P(\text{observed} \mid \text{true})$

		To		
		Forest	Crop	Grass
From	Forest	0.97	0	0.03
	Crop	0.02	0.8	0.18
	Grass	0.02	0.08	0.9

True	Prob. of observing
Forest	0.9
Crop	0.5
Grass	0.7

## Posterior distribution of LUC data cubes

[peterlevy.github.io/reproducibility\\_esa](https://peterlevy.github.io/reproducibility_esa)

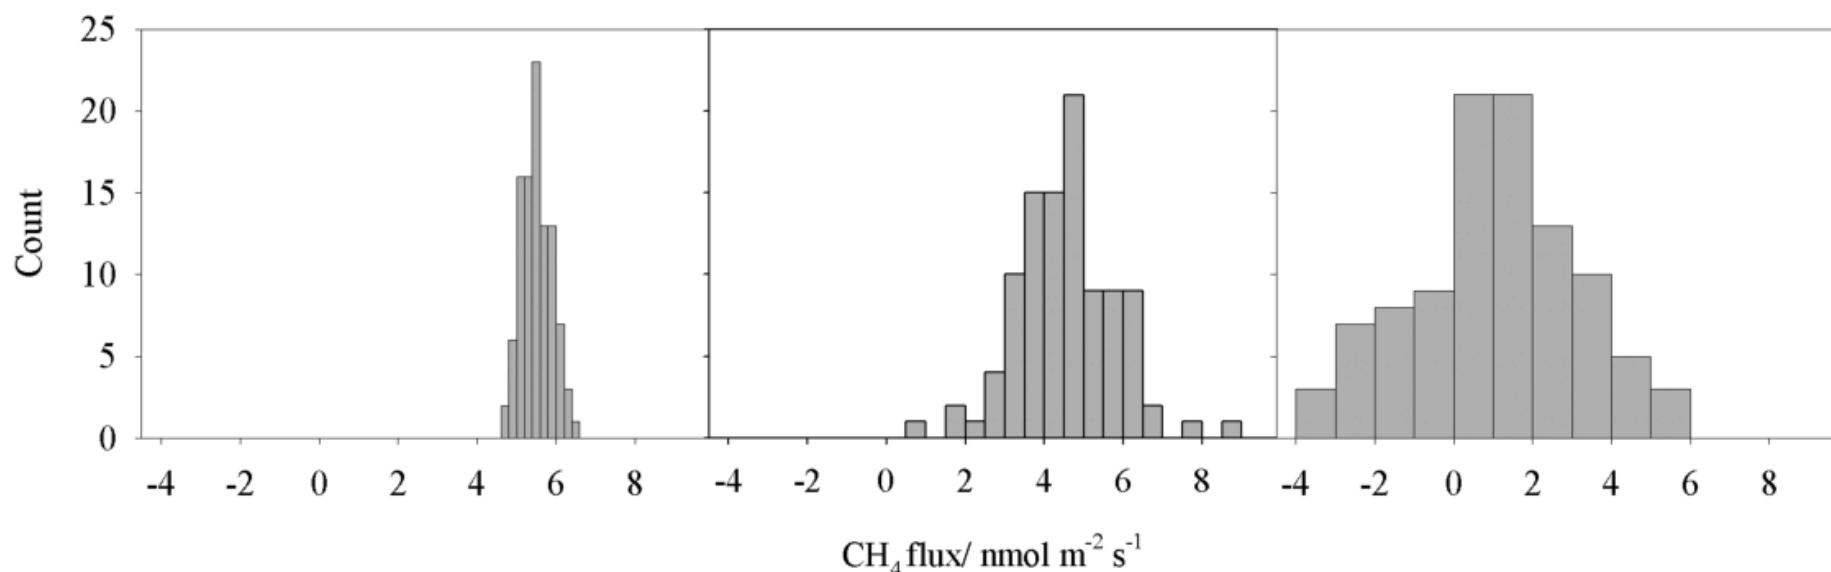

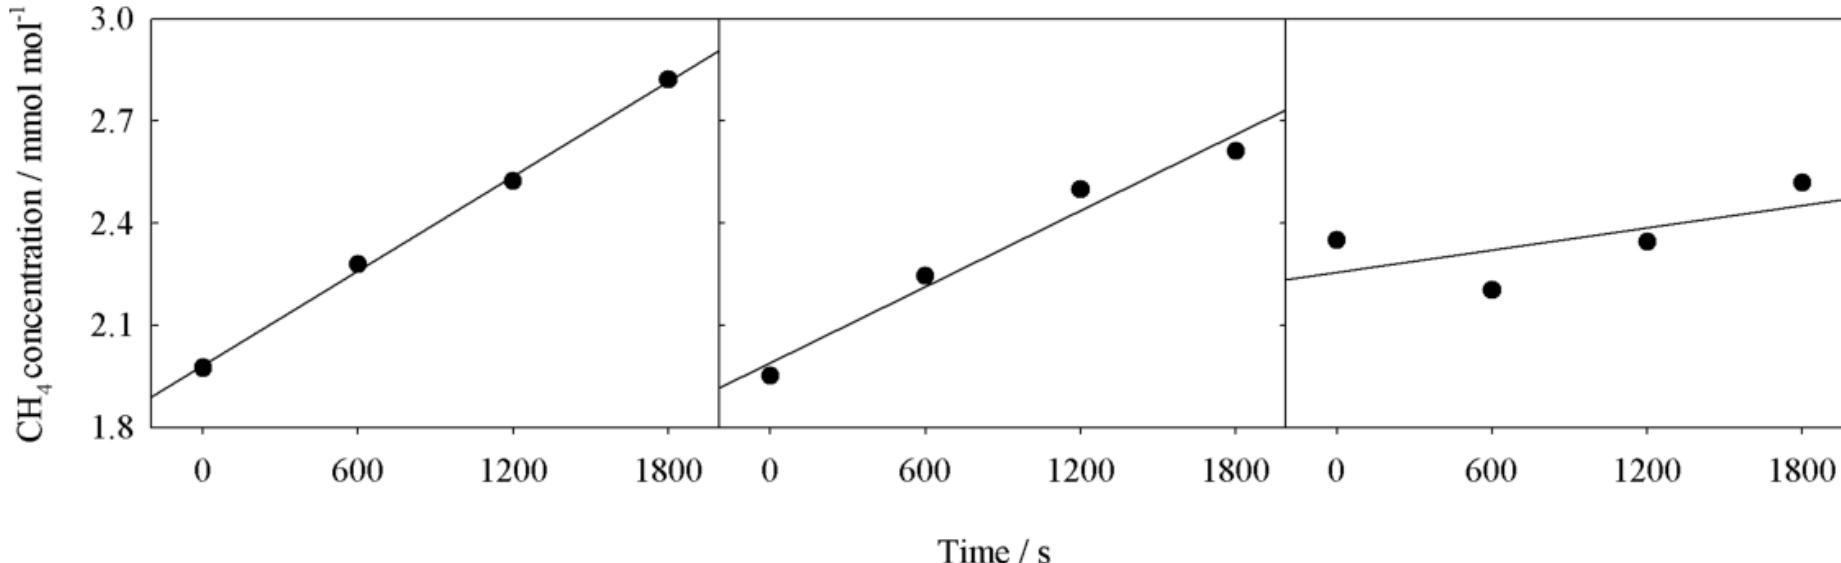

UKCEH

# Example: soil gas emissions

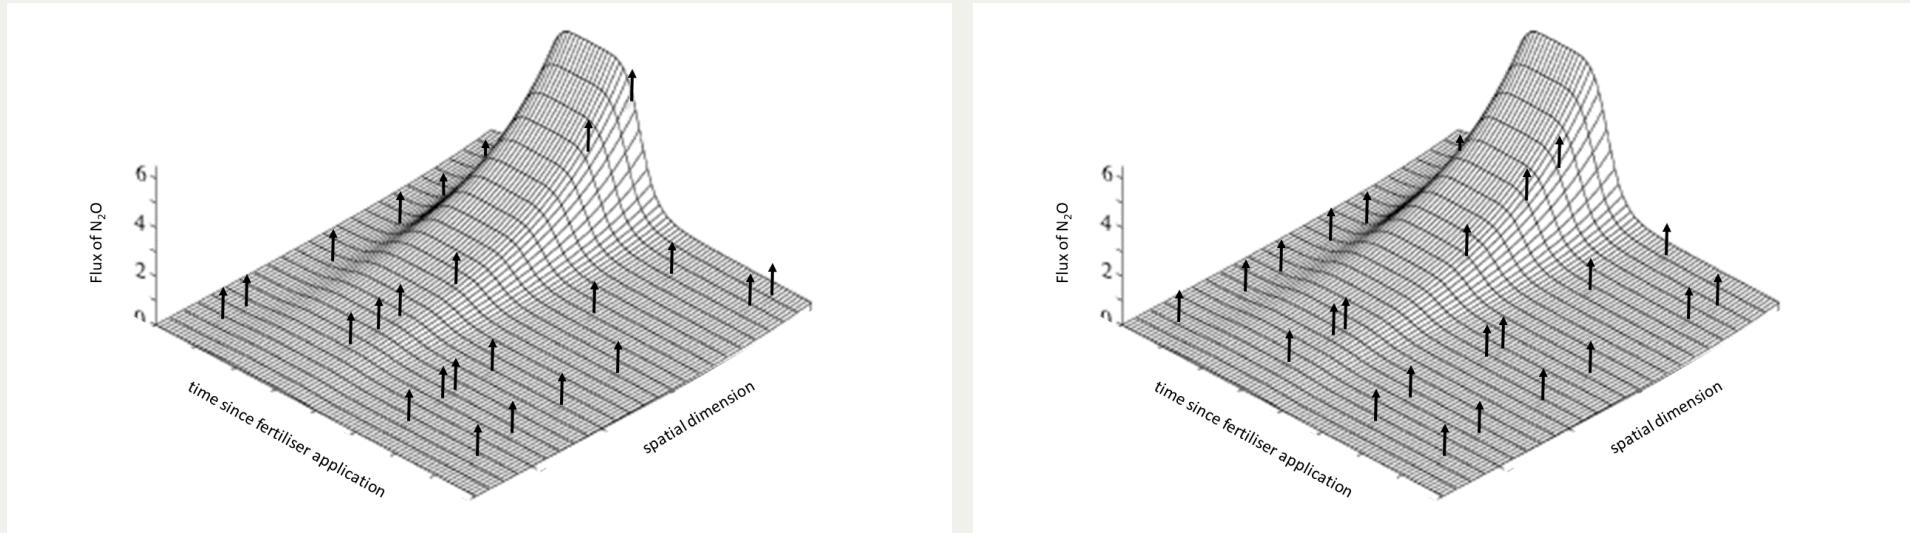

# Example: soil gas emissions

# Propagate the uncertainty in each measurement ...

# Example: soil gas emissions

... and in the spatio-temporal extrapolation ...

# Example: soil gas emissions

... to give posterior uncertainty in treatment effects.

# Summary

- Reproducibility (credibility) crisis arises from:
  - information architecture i.e. filtering
  - misuse of null-hypothesis testing
- In ecology, measurement is difficult & indirect ->
  - low statistical power
  - bias in obs process
- Represent the uncertainty in data & obs process
- Suggests Bayesian approach
